## 5 Traditional coupled-cluster theory

**Definition 5.1.** Traditional coupled-cluster theory. A wave operator maps a determinant into a correlated wavefunction,  $\Psi = \Omega \Phi$ . The coupled-cluster Ansatz is characterized by an exponential parametrization of the wave operator.

$$H_{c}\Psi_{CC} = E_{c}\Psi_{CC} \qquad \Psi_{CC} \equiv \exp(T)\Phi \qquad T \equiv T_{1} + T_{2} + \dots + T_{n} \qquad T_{k} \equiv \left(\frac{1}{k!}\right)^{2} t_{a_{1} \dots a_{k}}^{i_{1} \dots i_{k}} \tilde{a}_{i_{1} \dots i_{k}}^{a_{1} \dots a_{k}} \tag{5.1}$$

The coupled-cluster Schrödinger equation can be projected onto the determinant basis to arrive at a series of equations

$$\langle \Phi | H_{c} | \Psi_{CC} \rangle = E_{c} \qquad \langle \Phi_{ij...}^{ab...} | H_{c} | \Psi_{CC} \rangle = E_{c} t_{ab...}^{ij...} \qquad (5.2)$$

which specify the coupled-cluster energy and the amplitudes,  $t_{ab\cdots}^{ij\cdots}$ . A different approach, known as traditional coupled-cluster (TCC) theory, first multiplies the Schrödinger equation on the left by the inverse of the wave operator

$$\overline{H}_{c}\Phi = E_{c}\Phi$$
  $\overline{H}_{c} \equiv \exp(-T)H_{c}\exp(T)$  (5.3)

to define an effective Hamiltonian,  $\overline{H}_c$ . The eigenvalue of this similarity-transformed Hamiltonian is the exact correlation energy,  $E_c$ , but its eigenstate is the reference determinant,  $\Phi$ , rather than the correlated wavefunction. Note that, unlike the true Hamiltonian,  $\overline{H}_c$  is non-Hermitian. Projection onto the determinant basis yields energy and amplitude equations

$$\langle \Phi | \overline{H}_{c} | \Phi \rangle = E_{c}$$
  $\langle \Phi_{ij...}^{ab...} | \overline{H}_{c} | \Phi \rangle = 0$  (5.4)

which look similar to eq 5.2, except that the right-hand side of the amplitude equations is now zero. The next few results show that the TCC similarity transformation removes disconnected terms in eq 5.2, of which  $E_c t_{ab\cdots}^{ij\cdots}$  is an example.

Theorem 5.1. The Hausdorff Expansion. 
$$e^{-X}Ye^X = \sum_{n=0}^{\infty} \frac{1}{n!} [\cdot, X]^n(Y)^{-2}$$

Proof: This follows from  $\frac{\partial^n}{\partial \lambda^n}e^{-\lambda X}Ye^{\lambda X}=[\cdot\,,X]^n(e^{-\lambda X}Ye^{\lambda X})$ , which we will prove by induction. This is trivially true for n=0. Assuming it holds for n, the following shows that it also holds for n+1, completing the induction.

$$\tfrac{\partial^{n+1}}{\partial \lambda^{n+1}} e^{-\lambda X} Y e^{\lambda X} = [\,\cdot\,,X]^n (\tfrac{\partial}{\partial \lambda} e^{-\lambda X} Y e^{\lambda X}) = [\,\cdot\,,X]^n (e^{-\lambda X} Y e^{\lambda X} X - X e^{-\lambda X} Y e^{\lambda X}) = [\,\cdot\,,X]^{n+1} (e^{-\lambda X} Y e^{\lambda X}) = [\,\cdot\,,X]^n (e^{-$$

Substituting this result into a Taylor expansion of  $e^{-\lambda X}Ye^{\lambda X}$  about  $\lambda=0$  evaluated at  $\lambda=1$  completes the proof.

**Example 5.1.** The Hausdorff expansion can be used to express the TCC effective Hamiltonian in powers of T.

$$\overline{H}_{c} = \exp(-T)H_{c}\exp(T) = H_{c} + [H_{c}, T] + \frac{1}{2!}[[H_{c}, T], T] + \frac{1}{3!}[[[H_{c}, T], T], T] + \frac{1}{4!}[[[H_{c}, T], T], T] + \cdots$$

This expansion can be further simplified by analyzing the commutators with T using Wick's theorem.

**Proposition 5.1.** If Q and Q' are normal ordered and one of them has an even operator count,  $[Q,Q'] = : \overline{Q'}Q' : - : \overline{Q'}Q : .$ 

Proof: By Wick's theorem,  $QQ' - Q'Q = \mathbf{i}QQ'\mathbf{i} + \mathbf{i}QQ'\mathbf{i} - \mathbf{i}Q'Q\mathbf{i} - \mathbf{i}Q'Q\mathbf{i}$ . The proposition follows from the fact that  $\mathbf{i}QQ'\mathbf{i} = \mathbf{i}Q'Q\mathbf{i}$  when one of the strings contains an even number of operators.

Corollary 5.1. TCC similarity-transformed operators,  $\overline{W} \equiv \exp(-T)W\exp(T)$ , can be evaluated as  $\overline{W} = (W\exp(T))_{\rm C}$ , where the subscript C denotes a restriction to connected diagrams.

Proof: Prop 5.1 implies [W,T] = :WT: and, by straightforward induction,  $[\cdot,T]^n(W) = :WTT \cdot \cdot \cdot T: = (WT^n)_C$ , since T has no contractions with operators to its right.<sup>3</sup> Applying thm 5.1 to  $\overline{W}$  and using this result completes the proof.

Remark 5.1. Applying corollary 5.1 to the coupled-cluster effective Hamiltonian gives the following expansion

$$\overline{H}_{c} = (H_{c} \exp(T))_{C} = (H_{c} + H_{c}T + \frac{1}{2!}H_{c}T^{2} + \frac{1}{3!}H_{c}T^{3} + \frac{1}{4!}H_{c}T^{4})_{C}$$

which ends at the fourth power because  $H_c$  is a linear combination of one- and two-particle operators, which can contract at most two and four T's, respectively. Using this result, the energy and amplitude equations are often written as

$$\langle \Phi | H_{c} \exp(T) | \Phi \rangle_{C} = E_{c}$$
  $\langle \Phi_{ij...}^{ab...} | H_{c} \exp(T) | \Phi \rangle_{C} = 0$  (5.5)

where the subscript C on the expectation value ket is shorthand for  $\langle \Phi_{ij\cdots}^{ab\cdots}|(H_{\rm c}\exp(T))_{\rm C}|\Phi\rangle$ .

 $<sup>^1\</sup>mathrm{See}$  https://en.wikipedia.org/wiki/Matrix\_similarity.

 $<sup>{}^{2}[\</sup>cdot,X]^{n}(Y)$  denotes a nested commutator,  $[\cdot\cdot\cdot][Y,X],X]\cdot\cdot\cdot,X$ . For n=0, we define  $[\cdot,X]^{0}(Y)\equiv Y$ .

 $<sup>^{3}</sup>$ This is easily seen from the diagram. It comes from the fact that T is composed entirely of quasi-particle creation operators.

Notation 5.1. The following is suggested notation for the diagonal and off-diagonal contributions to the Fock operator.

where the excitation level  $\pm 1$  contributions to  $H_0$  have been omitted because its interaction tensor is diagonal.

Remark 5.2. It can be shown that the determinant basis forms an eigenbasis for the diagonal part of the Fock operator.<sup>4</sup>

$$H_0 \Phi_{i_1 \cdots i_k}^{a_1 \cdots a_k} = \mathcal{E}_{i_1 \cdots i_k}^{a_1 \cdots a_k} \Phi_{i_1 \cdots i_k}^{a_1 \cdots a_k} \qquad \qquad H_0 \equiv f_p^p \tilde{a}_p^p \qquad \qquad \mathcal{E}_{q_1 \cdots q_k}^{p_1 \cdots p_k} \equiv \sum_{r=1}^k f_{p_r}^{p_r} - \sum_{r=1}^k f_{q_r}^{q_r} \qquad (5.7)$$

Noting that  $H_0$  is Hermitian, this implies  $\langle \Phi_{ij\cdots}^{ab\cdots}|H_0\exp(T)|\Phi\rangle = \mathcal{E}_{ij\cdots}^{ab\cdots}\langle \Phi_{ij\cdots}^{ab\cdots}|\exp(T)|\Phi\rangle = \mathcal{E}_{ij\cdots}^{ab\cdots}t_{ab\cdots}^{ij\cdots}$ . This can be used to rearrange the amplitude equation in (5.5) as follows, which defines the working equations used to iteratively solve TCC.

$$t_{ab\cdots}^{ij\cdots} = (\mathcal{E}_{ab\cdots}^{ij\cdots})^{-1} \langle \Phi_{ab\cdots}^{ij\cdots} | V_c \exp(T) | \Phi \rangle_C \qquad V_c \equiv H_c - H_0 = f_p^q (1 - \delta_p^q) \tilde{a}_q^p + \frac{1}{4} \overline{g}_{pq}^{rs} \tilde{a}_{rs}^{pq}$$
 (5.8)

In Møller-Plesset perturbation theory,  $H_0$  is known the zeroth order Hamiltonian and  $V_c$  is the perturbation. These operators are also known as the model Hamiltonian and fluctuation potential, respectively.

**Definition 5.2.** Excitation level. The excitation level of a graph equals the net number of particles or quasi-particles it creates, divided by two. For example, the quasi-particle excitation levels of the  $T_1$ ,  $T_2$  and  $T_3$  operators are 1, 2, and 3, respectively, and that of  $\tilde{a}_{abcd}^{ijkl}$  is -4. A convenient rule for evaluating reference expectation values is that the total excitation level of a closed graph must balance out to zero.

**Example 5.2.** The excitation levels in the quasi-particle expansions of one- and two-particle operators are as follows.

$$\bigoplus_{(0)} = \bigoplus_{(0)} + \bigoplus_{(-1)} + \bigoplus_{(-1)} + \bigoplus_{(0)} + \bigoplus_{(-1)} + \bigoplus$$

**Example 5.3.** The CCSDTQ equations. Truncating the cluster operator at quadruples,  $T \approx T_1 + T_2 + T_3 + T_4$ , gives the CCSDTQ approximation. The resulting singles, doubles, triples, and quadruples amplitude equations are given by

$$\begin{split} t_a^i &= (\mathcal{E}_a^i)^{-1} \langle \Phi_i^a | V_{\text{C}} (1 + T_1 + T_2 + T_3 + \frac{1}{2} T_1^2 + T_1 T_2 + \frac{1}{3!} T_1^3) | \Phi \rangle_{\text{C}} \\ t_{ab}^{ij} &= (\mathcal{E}_{ab}^{ij})^{-1} \langle \Phi_{ij}^{ab} | V_{\text{C}} (1 + T_1 + T_2 + T_3 + T_4 + \frac{1}{2} T_1^2 + T_1 T_2 + T_1 T_3 + \frac{1}{2} T_2^2 + \frac{1}{3!} T_1^3 + \frac{1}{2} T_1^2 T_2 + \frac{1}{4!} T_1^4) | \Phi \rangle_{\text{C}} \\ t_{abc}^{ijk} &= (\mathcal{E}_{abc}^{ijk})^{-1} \langle \Phi_{ijk}^{abc} | V_{\text{C}} (T_2 + T_3 + T_4 + T_1 T_2 + T_1 T_3 + \frac{1}{2} T_2^2 + T_1 T_4 + T_2 T_3 + \frac{1}{2} T_1^2 T_2 + \frac{1}{2} T_1^2 T_3 + \frac{1}{2} T_1 T_2^2 + \frac{1}{3!} T_1^3 T_2) | \Phi \rangle_{\text{C}} \\ t_{abcd}^{ijkl} &= (\mathcal{E}_{abcd}^{ijkl})^{-1} \langle \Phi_{ijkl}^{abcd} | V_{\text{C}} (T_3 + T_4 + T_1 T_3 + \frac{1}{2} T_2^2 + T_1 T_4 + T_2 T_3 + T_2 T_4 + \frac{1}{2} T_3^2 + \frac{1}{2} T_1^2 T_3 + \frac{1}{2} T_1 T_2^2 + \frac{1}{2} T_1^2 T_4 \\ &\quad + T_1 T_2 T_3 + \frac{1}{3!} T_1^3 T_3 + \frac{1}{2!2!} T_1^3 T_2^2) | \Phi \rangle_{\text{C}} \end{split}$$

where several contributions to  $\exp(T_1 + T_2 + T_3 + T_4)$  have been omitted either because the excitation levels do not balance or because they require one of the cluster operators to be disconnected from the Hamiltonian.

<sup>&</sup>lt;sup>4</sup>The proof is as follows. First, note that  $a_p^p \Phi_\sigma = n_p^\sigma \Phi_\sigma$ , where  $n_p^\sigma$  is the occupation of  $\psi_p$  in  $\Phi_\sigma$ . By Wick's theorem,  $a_p^p = \tilde{a}_p^p + n_p^{\rm ref}$ , where  $n_p^{\rm ref}$  denotes the occupation of  $\psi_p$  in  $\Phi$ . Therefore,  $\tilde{a}_p^p \Phi_\sigma = (n_p^\sigma - n_p^{\rm ref})\Phi_\sigma$  and  $H_0\Phi_\sigma = \left(\sum_{p \in \Phi_\sigma} f_p^p - \sum_{p \in \Phi} f_p^p\right)\Phi_\sigma$ .

**Definition 5.3.** Isomorphism. For any invertible map  $S: \overline{V} \to V$ , we can express operators and vectors on V as

$$A = S\overline{A}S^{-1} \qquad |v\rangle = S|\overline{v}\rangle \qquad \langle v| = \langle \overline{v}|S^{-1} \qquad (5.9)$$

in terms of operators and vectors on  $\overline{V}$ . Note that the transformed bra and ket,  $\langle \overline{v}|$  and  $|\overline{v}\rangle$ , corresponding to v are not adjoints unless the transformation is unitary,  $S^{-1} = S^{\dagger}$ . The similarity-transformed operator  $\overline{A}$  retains all of the basis-independent properties of A, such as its trace, determinant, and eigenvalue spectrum, and its matrix elements satisfy  $\langle \overline{v}|\overline{A}|\overline{v}'\rangle = \langle v|A|v'\rangle$ . More broadly, the invertibility of S implies an isomorphism between V and  $\overline{V}$ , such that all statements about V are in one-to-one correspondence with statements about  $\overline{V}$  under this transformation.

**Remark 5.3.** Since exponential operators are automatically invertible, the TCC wave operator defines a similarity transformation of Fock space into itself. The image of the Schrödinger equation under this transformation is as follows

$$\overline{H}_{e} | \overline{\Psi}_{k} \rangle = E_{k} | \overline{\Psi}_{k} \rangle \qquad \langle \overline{\Psi}_{k} | \overline{H}_{e} = \langle \overline{\Psi}_{k} | E_{k} \rangle \qquad \overline{H}_{e} = \exp(-T) H_{e} \exp(T) \\
| \overline{\Psi}_{k} \rangle = \exp(-T) | \Psi_{k} \rangle \\
\langle \overline{\Psi}_{k} | = \langle \Psi_{k} | \exp(T) \rangle \qquad (5.10)$$

where the  $k^{\text{th}}$  left and right eigenstates are not adjoints because  $\exp(T)$  is inherently non-unitary. In TCC, T is determined by the requirement that the ground-state right eigenvector of  $\overline{H}_e$  be the reference determinant,  $|\overline{\Psi}_0\rangle \stackrel{!}{=} |\Phi\rangle$ .

**Definition 5.4.** Equation-of-motion coupled-cluster theory. Expanding the left and right eigenstates of  $\overline{H}_e$  in the determinant basis leads to the equation-of-motion (EOM) coupled-cluster equations

$$\overline{H}_e^{\ k}R|\Phi\rangle = E_k^{\ k}R|\Phi\rangle \quad R = R_0 + R_1 + \dots + R_n$$

$$\langle \Phi|^k L \overline{H}_e = \langle \Phi|^k L E_k \quad L = L_0 + L_1 + \dots + L_n$$

$$\langle \Phi|^k L^l R|\Phi\rangle \stackrel{!}{=} \delta_{kl} \tag{5.11}$$

which are analogous to the configuration interaction eigenvalue equation,  ${}^kR$  and  ${}^kL$  being linear excitation and deexcitation operators analogous to C and  $C^{\dagger}$ . The condition on the right indicates that left and right eigenstates are chosen to form a biorthonormal system by normalizing the overlap of the  $k^{\text{th}}$  left and right eigenfunctions to equal one. Observable expectation values are given by  $\langle \Psi_k | W | \Psi_k \rangle = \langle \Phi | {}^k L \, \overline{W} \, {}^k R | \Phi \rangle$  in terms of left and right EOM coefficients. Transition matrix elements are given by  $\langle \Psi_k | W | \Psi_l \rangle = \langle \Phi | {}^k L \, \overline{W} \, {}^l R | \Phi \rangle$ .

**Definition 5.5.** The coupled-cluster Lagrangian. The ground-state TCC equations are equivalent to requiring  ${}^{0}R = 1$ , which implies  ${}^{0}L_{0} = 1$  from the biorthonormality condition. Therefore, the ground-state left eigenvector has the form

$$^{0}L = 1 + \Lambda \qquad \qquad \Lambda = \Lambda_{1} + \dots + \Lambda_{n} \qquad \qquad \Lambda_{k} \equiv \left(\frac{1}{k!}\right)^{2} \lambda_{i_{1} \dots i_{k}}^{a_{1} \dots a_{k}} \tilde{a}_{a_{1} \dots a_{k}}^{i_{1} \dots i_{k}} \tag{5.12}$$

and the ground-state energy can be written as follows, in an expression known as the *coupled-cluster Lagrangian*.

$$\langle \Psi_0 | H_e | \Psi_0 \rangle = \langle \Phi | (1 + \Lambda) \overline{H}_e | \Phi \rangle \equiv \mathcal{L}(\mathbf{t}, \lambda) \tag{5.13}$$

To see why this constitutes a Lagrangian, note that setting its gradient with respect to  $\lambda_{i_1\cdots i_k}^{a_1\cdots a_k}$  equal to zero yields the TCC amplitude equations of eq 5.4. If these are satisfied, the  $\lambda$ -dependent part of the equation vanishes and the Lagrangian returns the coupled-cluster energy:  $\langle \Phi | \overline{H}_e | \Phi \rangle = E_e$ . Therefore, the  $\lambda$  coefficients can be viewed as Lagrange multipliers enforcing the TCC amplitude equations as a constraint.

**Definition 5.6.** The coupled-cluster lambda equations. Setting the gradient of  $\mathcal{L}$  with respect to  $t_{a_1 \cdots a_k}^{i_1 \cdots i_k}$  equal to zero gives the coupled-cluster lambda equations, which determine the Lagrange multpliers.

$$\langle \Phi | (1+\Lambda) H_{c} \exp(T) | \Phi_{i_{1} \cdots i_{k}}^{a_{1} \cdots a_{k}} \rangle_{C} \stackrel{!}{=} 0$$

$$(5.14)$$

The subscript C now denotes that  $H_c$  is connected both to the ket and to the T operators. This can be rearranged as<sup>5</sup>

$$\lambda_{i_1\cdots i_k}^{a_1\cdots a_k} = (\mathcal{E}_{a_1\cdots a_k}^{i_1\cdots i_k})^{-1} \langle \Phi | (1+\Lambda)V_{\mathbf{c}} \exp(T) | \Phi_{i_1\cdots i_k}^{a_1\cdots a_k} \rangle_{\mathbf{C}}$$

$$(5.15)$$

which sets up the iterative procedure for determining  $\lambda_{i_1\cdots i_k}^{a_1\cdots a_k}$  from a given set of amplitudes.

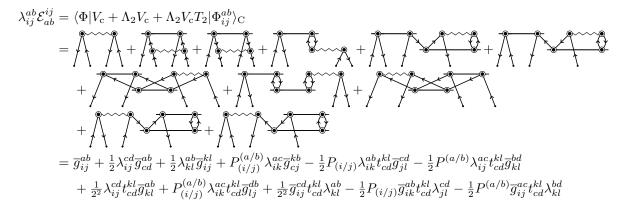

<sup>&</sup>lt;sup>5</sup>Note that  $\langle \Phi | \Lambda H_0 T^p | \Phi_{i_1 \cdots i_k}^{a_1 \cdots a_k} \rangle_{\mathbb{C}} = 0$  for  $p \geq 1$ , since the model Hamiltonian can only connect to one operator on either side.

**Example 5.4.** The CCSD lambda equations. Truncating the wave operator at doubles,  $T \approx T_1 + T_2$ , gives the CCSD approximation. The resulting singles and doubles lambda equations are given by the following

$$\lambda_{i}^{a} = (\mathcal{E}_{a}^{i})^{-1} \langle \Phi | V_{c} (1+T_{1}) + \Lambda_{1} V_{c} (1+T_{1}+T_{2}+\frac{1}{2}T_{1}^{2}) + \Lambda_{2} V_{c} (1+T_{1}+T_{2}+\frac{1}{2}T_{1}^{2}+T_{1}T_{2}) | \Phi_{i}^{a} \rangle_{C}$$
$$\lambda_{ij}^{ab} = (\mathcal{E}_{ab}^{ij})^{-1} \langle \Phi | V_{c} + \Lambda_{1} V_{c} (1+T_{1}) + \Lambda_{2} V_{c} (1+T_{1}+T_{2}+\frac{1}{2}T_{1}^{2}) | \Phi_{ij}^{ab} \rangle_{C}$$

where we have omitted any contributions to  $\exp(T_1 + T_2)$  that vanish.

**Example 5.5.** Assuming Brillouin's theorem holds, the CCD lambda equations are as follows.

Remark 5.4. The Hellmann-Feynman theorem. If the Hamiltonian depends on a parameter  $\xi$ , such as a nuclear coordinate or an electric field strength, we can express the Schrödinger equation as a function of that parameter

$$H_e(\xi)\Psi(\xi) = E_e(\xi)\Psi(\xi) \qquad \langle \Psi(\xi)|\Psi(\xi)\rangle \stackrel{!}{=} 1 \qquad (5.16)$$

Then the total derivative of the energy  $E_e(\xi) = \langle \Psi(\xi)|H(\xi)|\Psi(\xi)\rangle$  with respect to  $\xi$  is given by the following.

$$\frac{dE_e(\xi)}{d\xi} = \langle \Psi(\xi) | \frac{\partial H_e(\xi)}{\partial \xi} | \Psi(\xi) \rangle + \langle \frac{\partial \Psi(\xi)}{\partial \xi} | H_e(\xi) | \underline{\Psi(\xi)} \rangle + \langle \underline{\Psi(\xi)} | H_e(\xi) | \frac{\partial \Psi(\xi)}{\partial \xi} \rangle$$
(5.17)

The second and third terms cancel by the Hellmann-Feynman theorem, which one can prove by substituting the Schrödinger equation into both terms and employing the derivative of the normalization condition with respect to  $\xi$ . In words, it says that the first derivative of the energy does not depend on the "response" of the wavefunction. More generally, for approximate methods, the wavefunction may be parametrized by a set of coefficients  $\mathbf{c}$  which are stationary in the sense that their energy gradient equals zero. Denoting the remaining non-stationary coordinates by  $\mathbf{p}$ , we have

$$\frac{dE_e(\xi)}{d\xi} = \frac{\partial E_e(\xi)}{\partial \xi} + \frac{\partial E_e}{\partial \mathbf{c}} \cdot \frac{d\mathbf{c}}{d\xi} + \frac{\partial E_e}{\partial \mathbf{p}} \cdot \frac{d\mathbf{p}}{d\xi} \qquad \qquad \frac{\partial E_e}{\partial \xi} = \langle \Psi(\mathbf{c}, \mathbf{p}) | \frac{\partial H_e(\xi)}{\partial \xi} | \Psi(\mathbf{c}, \mathbf{p}) \rangle$$
(5.18)

which applies to configuration interaction and other variational methods. For most methods  $\mathbf{p}$  will include parameters which determine the molecular orbital coefficients, since the shape of the Hartree-Fock orbitals depends on  $\xi$ . When  $\xi$  is a nuclear coordinate, the atomic-orbital basis functions themselves change<sup>6</sup> and we must include parameters to account for this as well. The Hellmann-Feynman theorem does not apply to TCC energy, which is not stationary in any of its parameters. However, it does apply to the coupled-cluster Lagrangian as follows.

$$\frac{d\mathcal{L}(\xi)}{d\xi} = \frac{\partial \mathcal{L}(\xi)}{\partial \xi} + \frac{\partial \mathcal{L}}{\partial \mathbf{t}} \cdot \frac{d\mathbf{t}}{d\xi} + \frac{\partial \mathcal{L}}{\partial \mathbf{\lambda}} \cdot \frac{d\mathbf{\lambda}}{d\xi} + \frac{\partial \mathcal{L}}{\partial \mathbf{p}} \cdot \frac{d\mathbf{p}}{d\xi} \qquad \frac{\partial \mathcal{L}(\xi)}{\partial \xi} = \langle \Phi(\mathbf{p}) | (1+\Lambda) \frac{\partial H(\xi)}{\partial \xi} \exp(T) | \Phi(\mathbf{p}) \rangle_{\mathbf{C}}$$
(5.19)

This is known as the *generalized Hellmann-Feynman theorem* for coupled-cluster theory. Note that one must solve both the amplitude equations and the lambda equations in order to evaluate the equation on the right.

<sup>&</sup>lt;sup>6</sup>The parameters defining the basis functions are constant, but their centers of origin move with the nuclei.
